#### Abstract

: Climate plays an important role in the development of any region. Rainfall and temperature are the two important climatic factors which determine the climatic condition of any place. Ahmednagar district is a drought-prone area and it is situated in the central part of Maharashtra state. Intergovernmental Panel on Climate Change (IPCC, [5]) reports, frequency of droughts as well as extreme events will be increase and rainfall pattern will also change which is a key factor influencing economic growth of the regions, especially in the country like India where the 70 percent people are directly or indirectly depends on agriculture. But agriculture is hanging on Monsoon, erratic in nature. It also has great variations in spatiotemporally, those fluctuations extremely damaging agriculture, food security, health and many more. Therefore, the present study has been conducted in order to help farmers, researchers, economists, and policymakers to make fast decisions for better planning propose with variations of rainfall.

Key words: - Climate, Rainfall distribution, Variability.

## INTRODUCTION:

Climate plays an important role in determining the agricultural, industrial and economic growth of any region. Climate includes factors like Temperature, Rainfall, Pressure, Wind, Humidity, Precipitation, etc. Temperature and Rainfall are the most important factors which directly affect the climate condition of any region. There is a slow and steady increase in the temperature which has a direct impact on rainfall. Rainfall is the cheapest source of water provided it is timely and adequate in quantity. But rainfall in the greater part of India is uncertain and highly unevenly distributed. Rainfall is the major parameter influencing the agriculture activity of man. In India agricultural economy entirely depends on the amount of rainfall received during monsoon season. Rainfall is the dominant single weather element influencing the intensity and location of the farming system and the farmer's choice of enterprise. It also becomes a climatic hazard to farming when it is characterized by
scantiness, concentration, intensity, variability, and unreliability.

Such a study would help in the selection of crops and in short-range weather forecasting. In order to obtain an optimum yield from agriculture, it requires proper knowledge about the agro-climatic situation that helps for cropping patterns and crop management.

## STUDY AREA:

The present study deals with the geographical perspectives of the rainfall distribution in Ahmednagar district. Ahmednagar is the largest district of Maharashtra State with a geographical area of 17418 sq. km. which is $5.66 \%$ of the area of Maharashtra State. It lies between $18^{\circ} 2^{\prime}$ to $19^{\circ}$ $9^{\prime} \mathrm{N}$ latitude and $73^{\circ} 9^{\prime}$ to $75^{\circ} 5^{\prime} \mathrm{E}$ longitude with covering 14 tehsils. The population of district is 4543157 (2011) and Out of total workers 75. 42\% are engaged in agriculture. The district has 1256500 ha Net Cropped Area (NCA) out of 330000 ha area ( $26.27 \%$ ) is under canal and well
irrigation and remaining about 926500 ha. (73.73 $\%$ ) the area is rain-fed.

Therefore, agricultural operations mainly depend on south-west Monsoon, but rainfall in the district is highly erratic. The average annual rainfall in the district is 447 mm (2017). The climate of the district is hot and dry, the average of temperature 90 c to 410 c. The district is mostly in the rain shadow region to the east of Western Ghats. From the western border of the district, the rainfall decreases rapidly towards the east. About $77 \%$ of the annual rainfall in the district is received during the south-west monsoon season, September is the rainiest month and remaining months receiving unevenly with showing monthly as well as annual rainfall variability.

## OBJECTIVES:

Present paper has an attempt to make an assessment of the rainfall variability of Ahmednagar District and to identify the assured rainfall zone in the study region.

## DATABASE AND METHODOLGY:

The study is based on the rainfall data collected from Indian Meteorological Department for twenty-five years, for the period 1993 to 2017. For the data analysis following formula has used. Presentation of result chloroplasts cartographic method is used. CV = Coefficient of variability of rainfall, $\mathrm{SD}=$ Standard deviation of rainfall, $\mathrm{X}=$ Mean of rainfall

$$
\text { C. V. }(\%)=\frac{S D}{x} \times 100
$$

$\mathrm{CV}=$ Coefficient of variability of rainfall, $\mathrm{SD}=$ Standard deviation of rainfall, $X=$ Mean of rainfall.

The present study is based on secondary data. Secondary data will be collected from social economic review, district census handbook of Ahmednagar district. The data has been obtained
from the related articles, research papers, reports, policies and plan documents of Government of India and Maharashtra. Some data has been obtained from websites of Govt. of India and Govt. of Maharashtra, Ahmednagar, Nic. in, was undertaken to know the environmental status. The rainfall data for 14 stations in and around the study area were collected and analysised. Rainfall conditions were studied season wise and Annual Rainfall was computed and used to draw the maps.

## RESULTS AND DISCUSSION:

Table No. 1 indicates the mean annual rainfall of the study region. The present study analyzed rainfall conditions of Ahmednagar district and demarked district in low, medium and high rainfall zones. Coefficient of Variation (CV) has been calculated, it was highly variable running between 23.93 to 40.43 percent during 1993 to 2017. There are 14 rain gauge stations located in different places in the study area, and these stations measure the precipitation throughout the year. The lowest rainfall (below 500 mm ) observed in most parts of Shirampur, Nevasa, Shrigonda, Parner, Sangamner, and Kopargaon tehsil Due to the scarcity of water most of sectors are affecting especially agriculture. Medium rainfall (500 - 600 mm .) zone covers a large area including Nagar, Rahuri, Shevgaon, Pathardi, Karjat, and Rahata tehsil. Akole and Jamkhed tahsil has experienced high rainfall (above 600 mm ) but a concentration of rainfall within only South-West Monsoon while reaming months is hot and dry, is creating a water scarcity problem. (Map No. 2).

## RAINFALL DISTRIBUTION:

The distribution of rainfall in Ahmednagar district is uneven, therefore the coefficient of variation (CV) is also varied (Fig.2).
e-ISSN 2347-517X

The coefficient of variation (CV) is defined as the ratio of the standard deviation to the mean. The coefficient of variation has been calculated, it running between 23.93 percent to 42.43 percent from 1993 to 2017. The highest variations in rainfall were observed in Akole tahsil (42.43 \%), that clearly shows that trends and the pattern of rainfall are highly changing during the last 25 years, damaging the agriculture, health, business; the lowest variations was observed in Nevasa tehsil (23.93\%). Study also shows that one tahsil covered by 'high', three tahsil is 'medium' and ten tehsils is 'low' variation.

## CONCLUSION:

Mean annual rainfall and variability of rainfall is not uniform in all parts of the Ahmednagar District. Jamkhed Tehsil received the highest ( 621 mm ) mean annual rainfall; whereas Kopargaon tehsil has received the lowest ( 428 mm ) mean annual rainfall. Rainfall variability affected agriculture practices in Ahmednagar District. There is a need for artificial water supply for agriculture development and increase agriculture production.
