Abstract
Abstract Different solvent extracts of the leaves of Acacia Arabica, Ailanthus excelsa, Alstonia scholaris, Callistemon lanceolants, Casurina equisetifolia, Catharanthus roseus, Grevelia robusta, Moringa oleifera, Psidium guava, Saraca indica, Tamarindus indicum, Vitex negundo and Thuja compacta were investigated for their antibacterial activity on Escherchia coli NCIM-2931, Proteus vulgaris NCIM-2857, Pseudomonas auriginosa NCIM-5029, Staphylococcus aureus NCIM-5021, Bacillus cereus NCIM-2155, Bacillus subtilis NCIM-2063, and Bacillus megaterium NCIM-2087. 50 µl of solvent extract is used to test antibacterial activity using agar well diffusion method with well size of 5 mm diameter using High sensitivity test agar medium. Acetone and Methanol extracts of Acacia Arabica, Callistemon lanceolants, Casurina equisetifolia, Psidium guava, Saraca indica, and Thuja compacta showed significant activity against tested bacteria. Psidium guava extracts in acetone, chloroform, methanol and petroleum ether, are active against all bacteria tested except Bacillus cereus. Saraca indica’s extract in acetone, chloroform, methanol and petroleum ether are active against all Gram positive bacteria tested.

Keywords
Key words: Solvent extracts, Antibacterial activity, agar well diffusion method.

Introduction
Introduction Medicinal plants form the backbone of traditional system of medicine in India. Pharmacological studies have acknowledged the value of medicinal plants as potential source of bioactive compounds (Prusti et.al., 2008). Phytochemicals from medicinal plants serve as lead compounds in drug discovery and design (Chakravarthy and Gode, 1985; Ebi and Ofoefule, 2000). Medicinal plants are rich source of novel drugs that forms the ingredients in traditional system of medicines, modern medicines, nutraceuticals, food supplements, folk medicines, pharmaceutical intermediates, bioactive principles and lead compounds in synthetic
drugs (Ncube, 2008). Nowadays multiple drug resistance has developed due to the indiscriminate use of commercial antimicrobial drugs commonly used in the treatment of infectious disease (Davis, 1994; Service, 1995). In addition to this problem, antibiotics are sometimes associated with adverse effects on the host including hypersensitivity, immune-suppression and allergic reactions (Ahmad et al., 1998). This situation forced scientists to search for new antimicrobial substances. Given the alarming incidence of antibiotic resistance in bacteria of medical importance (Monroe and Polk, 2000), there is a constant need for new and effective therapeutic agents (Bhavani and Ballow, 2000). Therefore, there is a need to develop alternative antimicrobial drugs for the treatment of infectious diseases from medicinal plants (Clark, 1996 and Cordell, 2000). Several screening studies have been carried out in different parts of the world. There are several reports on the antimicrobial activity of different herbal extracts in different regions of the world (Chung et al., 2004, De Boer et al., 2004, Nair and Chanda, 2004, Nair et al., 2005).

**Material and Method**

Materials and Methods Test Organisms Escherichia coli NCIM 2931, Proteus vulgaris NCIM 2857, Pseudomonas aureginosa NCIM 5029, Bacillus cereus NCIM 2155, Bacillus subtilis NCIM 2063, Bacillus megaterium and staphylococcus aureus NCIM 5021 these cultures were obtained from the National Collection of Industrial microorganisms, Pune. Plants Acacia arabica, Ailanthus excelsa, Alstonia scholaris, Casurina equisitifolia, Catharanthus roseus, Callistemon lanceolantus, Grevellia robusta, Moringa oleifera, Psidium guayava, Saraca indica, Tamarindus indicum, Thuja compacta and Vitex negundo. Aqueous extraction Ten grams of dried plant material was extracted with 100 ml of distilled water for 6 h. at slow heat. Every 2 h. it was filtered through 8 layers of muslin cloth and centrifuged at 5000 g for 15 min. The supernatant was collected. This procedure was repeated twice and after 6 h the supernatant was concentrated to make the final volume one fifth of the original.
volume (Parekh, 2005). The extract was then autoclaved at 1210°C and 15 lbs pressure, and stored at 40°C. Solvent Extraction Ten grams of dried plant material was extracted with 100 ml of solvent kept on a rotary shaker for 24 h. Thereafter, it was filtered and centrifuged at 5000 g for 15 min. The supernatant was collected and the solvent was evaporated to make the final volume one-fifth of the original volume (Parekh, 2005). It was stored at 40°C in airtight bottles for further studies. Antibacterial assay The antibacterial activity of different plant species was evaluated by agar well diffusion (Perez et al., 1990) for solvent extracts using Hi-sensitivity test agar (M 485) for the assay. The microorganism was activated by inoculating a loopful of the strain in 5 ml of Hi-sensitivity test broth and broth was incubated at 350°C+ 0.50°C for 18-20 hrs. After incubation a loopful of actively growing culture was inoculated into 10 ml of Hi-sensitivity broth. Broth was incubated at 350°C+0.50°C for 6-8 hours. 0.5 ml inoculums was inoculated in to the Hi-sensitivity test agar media and after proper homogenization it was poured into 100 mm petri dishes. For the agar well diffusion, a well was made in the seeded plates with the help of a cup-borer (5 mm). The test compound was introduced in to the well and all the plates were incubated at 350°C+ 0.50°C for 24 hrs. Microbial growth was determined by measuring the diameter of the zone of inhibition are presented (Table-1).

**Result and Discussion**

Results and Discussions Results are given in Table No.1. Successful prediction of botanical compounds from plant material is largely dependent on the type of solvent used in the extraction procedure. Traditional healers use primarily water as the solvent but in our studies we found that plant extracts in organic solvent (Acetone, Chloroform, Methanol and Petroleum ether) provided more consistent antimicrobial activity compared to those extracted in water. These observations can be rationalized in terms of the polarity of the compounds being extracted by each solvent and, in addition to their intrinsic bioactivity, by
their ability to dissolve or diffuse in the media used in the assay. Ailanthus excelsa, Alstonia scholaris, Grevellia robusta, Moringa oleifera (only water extract is active), Tamarindus indica extracts were totally inactive against all the microorganisms tested. The plants that exhibited antibacterial activity to a certain degree were Acacia Arabica, Callistemon lanceolantus, Casurina equisetifolia, Psidium guajava, Saraca indica and Thuja compacta. Acetone and methanol extract of Acacia Arabica were active against all the bacteria except E. coli. Methanol extract of Callistemon lanceolantus is active against Pseudomonas aeruginosa, Staphylococcus aureus, Bacillus cereus, Bacillus subtilis and Bacillus megaterium. Acetone, methanol and petroleum ether extracts of Psidium guajava are active against all bacteria (Fig. 1 and 2) except Bacillus cereus. Acetone, chloroform, methanol and petroleum ether extracts of Saraca indica are active against Staphylococcus aureus (Fig 4), Bacillus cereus, Bacillus subtilis (Fig 3), and Bacillus megaterium where as water extract is active against Bacillus subtilis, and Bacillus megaterium. Acetone extracts of Thuja compacta is active against all Gram positive bacteria. Chloroform extract is active against Proteus vulgaris, Bacillus subtilis (Fig 5), and Bacillus megaterium (Fig 6). Methanol and petroleum ether extracts are active against Staphylococcus aureus, Bacillus subtilis, and Bacillus megaterium where as water extract is inactive against all the microorganisms. Acetone and chloroform extracts of Vitex negundo are active against Bacillus subtilis, and Bacillus megaterium. Methanol extract is active against Proteus vulgaris, Bacillus subtilis, and Bacillus megaterium. Petroleum ether and water extracts are inactive against all the microorganisms. Out of 13 plant species, Callistemon lanceolantus, Psidium guajava, Saraca indica and Thuja compacta showed significant activity. the plant extracts were more active against the Gram positive bacteria. This is in agreement with previous reports that plant extracts are more active against Gram positive than against Gram negative bacteria (Vlietinck et.al., 1995, Rabe et.al., 1997). From our investigation of screening different plant species, the results obtained confirm
the therapeutic potency of some plants used in traditional medicine. The results of the present study support the folkloric usage of the studied plants and suggest that some of the plant extracts possess compounds with antibacterial properties that can be used as antimicrobial agents in new drugs for the therapy of infectious diseases caused by pathogens. The most active extracts can be subjected to isolation of the therapeutic antimicrobials and undergo further pharmacological evaluation. Screening of various natural organic compounds and identifying active agents is the need of the hour, because successful prediction of lead molecule and drug like properties at the onset of drug discovery will pay off later in drug development.

Conclusion
From our investigation of screening different plant species, the results obtained confirm the therapeutic potency of some plants used in traditional medicine. The results of the present study support the folkloric usage of the studied plants and suggest that some of the plant extracts possess compounds with antibacterial properties that can be used as antimicrobial agents in new drugs for the therapy of infectious diseases caused by pathogens. The most active extracts can be subjected to isolation of the therapeutic antimicrobials and undergo further pharmacological evaluation. Screening of various natural organic compounds and identifying active agents is the need of the hour, because successful prediction of lead molecule and drug like properties at the onset of drug discovery will pay off later in drug development.
